NURa Hand-in 3

Name (Student number)

Date

For each halo-mass bin, I fit the same parametric profile (; , ,) n(x;a,b,c) separately. This yields five different best-fit parameter sets (, ,) (a,b,c), one for each mass bin. The normalization A is not an independent fit parameter, but is recalculated from , , a,b,c for each trial model. Because the radial coordinate is normalized by the virial radius, the model describes the dimensionless shape of the satellite distribution, allowing that shape to vary with halo mass.

Write a short description of your solution in each section. Explain your choices. Explicitly draw conclusions from your results.

You can refer to selected lines of code where you think it is necessary. However, you must provide the full code relevant to each (sub)question below it.

Don't forget to describe your figures and mention what conclusions you draw from them!

1 Satellite galaxies around a massive central

1.1 (1a) Maximum of N(x)

Explain the maximization algorithm used.

The maximum of $N(x)$ is found at:

$$x_{\max} \approx 0.000000$$

$$N(x_{\max}) \approx 0.000000$$

1.1.1 Code for N(x) maximization

NOTE: all code is reproduced below as an example, show only the relevant lines for this exercise here instead.

```
# imports
import matplotlib.pyplot as plt
import numpy as np

def readfile(filename):
    """
    Helper function to read in the satellite galaxy data from the provided text
    files.

    Parameters
```

```python
    ----------
    filename : str
        The name of the file to read in.

    Returns
    -------
    radius : ndarray
        The virial radius for all the satellites in the file.
    nhalo : int
        The number of halos in the file.
    """
    f = open(filename, "r")

1.2 (1b) χ^2-fit

Argue the choices of your binning. Explain the minimization routine used. Bonus points for a correctly implemented derivative-based routine.

Table 1: Best-fit parameters for χ^2 fits.

Dataset	N_{sat}	χ^2	a	b	c
m11	0.00000	0.00000	0.00000	0.00000	0.00000
m12	0.00000	0.00000	0.00000	0.00000	0.00000
m13	0.00000	0.00000	0.00000	0.00000	0.00000
m14	0.00000	0.00000	0.00000	0.00000	0.00000
m15	0.00000	0.00000	0.00000	0.00000	0.00000

Figure 1: Fit of the satellite number density profile using the chi-squared method.

1.3 (1c) Poisson ln-likelihood fit

Explain how you determine the Poisson ln-likelihood. Describe the optimization method used. How do your best fit parameters differ from the ones obtained in (1b)? Why?

Table 2: Best-fit parameters for χ^2 fits.

Dataset	llh	a	b	c
m11	0.00000	0.00000	0.00000	0.00000
m12	0.00000	0.00000	0.00000	0.00000
m13	0.00000	0.00000	0.00000	0.00000
m14	0.00000	0.00000	0.00000	0.00000
m15	0.00000	0.00000	0.00000	0.00000

Figure 2: Fit of the satellite number density profile using the Poisson log-likelihood method.

1.3.1 Code for Poisson ln-likelihood fit

NOTE: all code is reproduced below as an example, show only the relevant lines for this exercise here instead.

```
# imports
import matplotlib.pyplot as plt
import numpy as np

1.4 (1d) Statistical tests

Table 3: Statistical tests for the χ^2 and Poisson ln-likelihood fits.

Method	Dataset	G	Q
χ^2	m11	0.00000	0.00000
χ^2	m12	0.00000	0.00000
χ^2	m13	0.00000	0.00000
χ^2	m14	0.00000	0.00000
χ^2	m15	0.00000	0.00000
Poisson	m11	0.00000	0.00000
Poisson	m12	0.00000	0.00000
Poisson	m13	0.00000	0.00000
Poisson	m14	0.00000	0.00000
Poisson	m15	0.00000	0.00000

What can you conclude from the results of the statistical tests?
